Small Project Report

My project is a Student Registration System developed on a local XAMPP server.

The system follows a client-server architecture.

- Client: The user interacts with the registration form through a web browser.
- Server: Apache runs the PHP scripts and processes the information submitted by the user.
- Database: MySQL stores the registered student information.

My system has five main layers:

1. Presentation layer: HTML and CSS display the registration form.
2. Controller layer: PHP receives requests from the client.
3. Business logic layer: PHP validates student information.
4. Data access layer: PHP communicates with MySQL using SQL queries.
5. Database layer: MySQL stores student records.

When a user enters their name, email and course and clicks Register:

1. The browser sends an HTTP POST request to the server.
2. PHP receives and validates the information.
3. The server sends an SQL query to MySQL.
4. MySQL saves the student information.
5. The server returns a success message to the browser.
